SYLLABUS

Course Purpose:

To enable students understand the fundamental principles of digital transmission systems as used in fixed and mobile telephony, wired and wireless computer networks, data storage and digital broadcasting.

Expected Learning Outcomes:

At the end of the course, students will be able to:

- (i) describe binary and duo binary pulse Amplitude Modulation (PAM);
- (ii) design digital coding schemes;
- (iii) derive error performance equations for digital modulation schemes(ASK,FSK,PSK,DPSK);
- (iv) state strengths and weaknesses of M-ary PSK with QAM signaling schemes;
- (v) design a basic digital communication systems.

Course Content:

Signal digitization: Pulse Amplitude Modulation (PAM), sampling theorems and sampling circuits, Pulse code modulation (PCM). Quantization and signal conditioning: Uniform and non-uniform quantization; companding methods; vocoders; signal-to- quantization noise ratio. Waveform coding: Pulse transmission, PCM, Pulse-shaping; Delta modulation; adaptive delta modulation; Differential Pulse Code Modulation (DPCM), M-ary encoding. Digital Modulation: Amplitude shift keying (ASK), Frequency Shift Keying (FSK), Phase Shift Keying (PSK), Quadrature Amplitude Modulation (QAM) and Differential Phase Shift Keying (DPSK). Signal recovery in ASK, FSK and PSK; Gaussian Minimum Shift Keying (GMSK); Performance comparison. Information theory: information sources, entropy, channel capacity; Source Coding; entropy coding. Error control: Error control coding techniques; Transmission errors; Error detection methods; intersymbol interference and the eye pattern; Linear block codes; Cyclic codes; convolution codes. Multiplexing: Frequency division multiplex (FDM), Time Division Multiplexing (TDM), plesiochronous digital hierarchy (PDH). Spread spectrum communication: Direct sequence and frequency hopping methods; synchronization, spreading codes and their generation. Data transmission: Local data transmission protocols (Ethernet, token ring); Modems; high Asymmetric Digital subscriber line (ADSL); Very-high Speed Digital subscriber line (VDSL), integrated services digital network (ISDN).

KEY POINTS ABOUT PCM

1. While PCM is a pulse modulation technique much like PWM, PAM or PPM.
2. PCM is digital while the others are either analogue in time or amplitude, i.e PCM pulses are discrete in time and amplitude unlike PAM, PWM or PPM.
3. Essential aspects of a PCM transmitter are sampling, quantizing and encoding.
4. PCM is not a modulation in the conventional sense because it does not rely on varying a characteristic of a carrier (amplitude, frequency or phase).

PCM TRANSMISSION PATH

- **PCM transmission path** refers to the path the the signal travels between the transmitter and the receiver.

HOW A PCM REPEATER WORKS

1. **A PCM repeater does the follows:**
 - a) **Receives a PCM signal**
 - b) Regenerates the signal by cleaning up noise and distortion
 - c) Retransmitting a fresh, reshaped signal matching the original signal quality
2. The use of repeaters enables long-distance transmission without significant signal degradation by periodically amplifying and reshaping the signal at repeater stations along the transmission path.

PCM RECEIVER – CONVERTING TO ANALOGUE SIGNAL

TYPES OF QUANTIZERS

MIDTREAD QUANTIZER

1. A **midtread quantizer** assumes values of the form ΔH_i where Δ is the step size and $H_i = 0, \pm 1, \pm 2, \pm 3, \dots$
2. It is called **mid-tread** because the origin lies in the middle of a tread of a staircase-like graph.

MIDRISER QUANTIZER

1. A mid-riser quantizer has output levels are given by $\frac{\Delta}{2}H_i$, where Δ is the step size and $H_i = \pm 1, \pm 2, \pm 3, \dots$
2. The origin lies in the middle of the rising part of the staircase-like characteristic graph.

PCM TRANSMISSION BANDWIDTH

1. Assume the a PCM encoder has q levels which are encoded to v bits.

2. We can infer

$$q = 2^v$$

3. The number of bits per second can be expressed as:

$$f_{pcm} = v f_s \quad \text{where } f_s \geq 2f_m \text{ (Nyquist criterion)}$$

4. It therefore follows that the bandwidth, BW of a PCM channel is bounded by:

$$BW_{pcm} \geq 2v f_m$$

EXAMPLE 1

1. A TV signal with a bandwidth of 4.2 MHz is transmitted using binary PCM system using 512 quantization levels. Determine
 - (a) Code word-length
 - (b) The PCM bandwidth/bit rate

SOLUTION

$$(a) \quad f_m = 4.2 \text{ MHz}$$
$$q = 2^v = 512$$

$$v = \log_2 512 = 9 \text{ bits}$$

$$(b) \text{ Bandwidth, BW} = v(2f_m) = 2 \times 9 \times 4.2 = 75.6 \text{ Mb/s}$$

CODING TECHNIQUES

BINARY ENCODING

- 1. Encoding** converts the quantized samples into a form that is more convenient for the purpose of transmission.
- 2. Encoding** is a one-to-one mapping of the quantized samples by using code elements or symbols of the required length per sample.

INVERTED FOLDED BINARY CODE

1. If only the amplitude digits of a folded binary code are complemented (1's changed to 0's and 0's to 1's), an inverted folded binary code results.
2. This code has the **advantage of higher density of 1's for small amplitude signals**, which are most probable for voice messages.
3. The higher density of 1's also **relieves some system timing errors**.

ADVANTAGES OF GREY CODE

- 1. Error reduction:** Due to the single bit change property, Gray code minimizes the chance of spurious outputs or glitches during state transitions.
- 2. Reliable in electromechanical systems:** Gray code is widely used in devices like rotary encoders as only one bit changes at a time, preventing misinterpretations.
- 3. Simplified logic design:** The predictable nature of Gray code simplifies the **design of circuits that need to interpret positional data**, as only one bit needs to be monitored for changes.

DISADVANTAGES OF GREY CODE

The main disadvantage of grey code is that performing arithmetic operations like addition or subtraction directly on Gray code numbers is complex and not readily achievable, and conversion to binary must be done for calculations.

PCM INTEGRATED CIRCUITS - MC14LC5480

1. The MC14LC5480 is a **general purpose per channel PCM Codec–Filter with pin selectable μ –Law or A–Law companding**, and is offered in 20–pin DIP, SOG, and SSOP packages.
2. MC14LC5480 performs **voice digitization and reconstruction as well as the band limiting and smoothing required for PCM systems**.
3. MC14LC5480 designed to **operate in both synchronous and asynchronous applications** and contains an on–chip precision reference voltage.

RECAP: ADVANTAGES OF PCM

1. PCM provides high noise immunity
2. Allows regeneration of clean signal by using repeaters placed between the transmitter and the receiver.
3. PCM signals can be stored for later use or retransmission with high fidelity
4. PCM signals can be encrypted more easily and to very high standards.

RECAP: DISADVANTAGES OF PCM

1. PCM requires complex circuitry to sample, quantize, code and decode.
2. PCM requires large bandwidth compared with that of the original analog signal, i.e

$$BW_{pcm} \geq 2vf_m$$
